LT1117/LT1117-2.85
LT1117-3.3/LT1117-5
800mA Low Dropout
Positive Regulators
Adjustable and Fixed 2.85V,
3.3V, 5V

FEATURES
- Space Saving SOT-223 Surface Mount Package
- Three-Terminal Adjustable or Fixed 2.85V, 3.3V, 5V
- Output Current of 800mA
- Operates Down to 1V Dropout
- Guaranteed Dropout Voltage at Multiple Current Levels
- 0.2% Line Regulation Max
- 0.4% Load Regulation Max

APPLICATIONS
- Active SCSI Terminators
- High Efficiency Linear Regulators
- Post Regulators for Switching Supplies
- Battery Chargers
- 5V to 3.3V Linear Regulators

DESCRIPTION
The LT1117 is a positive low dropout regulator designed to provide up to 800mA of output current. The device is available in an adjustable version and fixed output voltages of 2.85V, 3.3V and 5V. The 2.85V version is designed specifically to be used in Active Terminators for the SCSI bus. All internal circuitry is designed to operate down to 1V input to output differential. Dropout voltage is guaranteed at a maximum of 1.2V at 800mA, decreasing at lower load currents. On chip trimming adjusts the reference/output voltage to within ±1%. Current limit is also trimmed in order to minimize the stress on both the regulator and the power source circuitry under overload conditions.

The low profile surface mount SOT-223 package allows the device to be used in applications where space is limited. The LT1117 requires a minimum of 10μF of output capacitance for stability. Output capacitors of this size or larger are normally included in most regulator designs.

Unlike PNP type regulators where up to 10% of the output current is wasted as quiescent current, the quiescent current of the LT1117 flows into the load, increasing efficiency.

The ● denotes specifications which apply over the full operating temperature range.

**Note 1:** See thermal regulation specification for changes in output voltage due to heating effects. Load regulation and line regulation are measured at a constant junction temperature by low duty cycle pulse testing.

**Note 2:** Dropout voltage is specified over the full output current range of the device. Dropout voltage is defined as the minimum input/output differential measured at the specified output current. Test points and limits are also shown on the Dropout Voltage curve.

**Note 3:** Minimum load current is defined as the minimum output current required to maintain regulation.

---

The LT1117 family of three-terminal regulators are easy to use. They are protected against short circuit and thermal overloads. Thermal protection circuitry will shutdown the regulator should the junction temperature exceed 165°C at the sense point. These regulators are pin compatible with older three-terminal adjustable regulators, offer lower dropout voltage and more precise reference tolerance. Reference stability over temperature is improved over older types of regulators.

Stability
The LT1117 family of regulators requires an output capacitor as part of the device frequency compensation. A minimum of 10µF of tantalum or 50µF of aluminum electrolytic is required. The ESR of the output capacitor should be less than 0.5Ω. Surface mount tantalum capacitors, which have very low ESR, are available from several manufacturers.

When using the LT1117 adjustable device the adjust terminal can be bypassed to improve ripple rejection.

When the adjust terminal is bypassed the required value of the output capacitor increases. The device will require an output capacitor of 22µF tantalum or 150µF aluminum electrolytic when the adjust pin is bypassed.

Normally, capacitor values on the order of 100µF are used in the output of many regulators to ensure good load transient response with large load current changes. Output capacitance can be increased without limit and larger values of output capacitance further improve stability and transient response.

Protection Diodes
In normal operation, the LT1117 family does not need any protection diodes. Older adjustable regulators required protection diodes between the adjust pin and the output and between the output and input to prevent over stressing the die. The internal current paths on the LT1117 adjust pin are limited by internal resistors. Therefore, even with capacitors on the adjust pin, no protection diode is needed to ensure device safety under short circuit conditions. The
adjust pin can be driven, on a transient basis, ±25V with respect to the output without any device degradation.

Diodes between input and output are not usually needed. The internal diode between the output and input pins of the device can withstand microsecond surge currents of 10A to 20A. Normal power supply cycling can not generate currents of this magnitude. Only with extremely large output capacitors, such as 1000µF and larger, and with the input pin instantaneously shorted to ground can damage occur. A crowbar circuit at the input of the LT1117 in combination with a large output capacitor could generate currents large enough to cause damage. In this case a diode from output to input is recommended, as shown in Figure 1.

Output Voltage

The LT1117 develops a 1.25V reference voltage between the output and the adjust terminal (see Figure 2). By placing a resistor between these two terminals, a constant current is caused to flow through R1 and down through R2 to set the overall output voltage. Normally this current is chosen to be the specified minimum load current of 10mA. Because I_{ADJ} is very small and constant when compared to the current through R1, it represents a small error and can usually be ignored. For fixed voltage devices R1 and R2 are included in the device.

Load Regulation

Because the LT1117 is a three-terminal device, it is not possible to provide true remote load sensing. Load regulation will be limited by the resistance of the wire connecting the regulator to the load. The data sheet specification for load regulation is measured at the output pin of the device. Negative side sensing is a true Kelvin connection, with the bottom of the output divider returned to the negative side of the load. Although it may not be immediately obvious, best load regulation is obtained when the top of the resistor divider (R1) is returned directly to the output pin of the device, not to the load. This is illustrated in Figure 3. Connected as shown, R_P is not multiplied by the divider ratio. If R1 were connected to the load, the effective resistance between the regulator and the load would be:

\[ R_P \times \frac{R_2 + R_1}{R_1} \]

\[ R_P = \text{Parasitic Line Resistance} \]

For fixed voltage devices the top of R1 is internally Kelvin connected, and the ground pin can be used for negative side sensing.
**APPLICATION HINTS**

**Thermal Considerations**

LT1117 series regulators have internal thermal limiting circuitry designed to protect the device during overload conditions. For continuous normal load conditions however, the maximum junction temperature rating of 125°C must not be exceeded.

It is important to give careful consideration to all sources of thermal resistance from junction to ambient. For the SOT-223 package, which is designed to be surface mounted, additional heat sources mounted near the device must also be considered. Heat sinking is accomplished using the heat spreading capability of the PC board and its copper traces. The thermal resistance of the LT1117 is 15°C/W from the junction to the tab. Thermal resistances from tab to ambient can be as low as 30°C/W. The total thermal resistance from junction to ambient can be as low as 45°C/W. This requires a reasonable sized PC board with at least one layer of copper to spread the heat across the board and couple it into the surrounding air.

Experiments have shown that the heat spreading copper layer does not need to be electrically connected to the tab of the device. The PC material can be very effective at transmitting heat between the pad area, attached to the tab of the device, and a ground plane layer either inside or on the opposite side of the board. Although the actual thermal resistance of the PC material is high, the Length/Area ratio of the thermal resistor between layers is small. The data in Table 1 was taken using 1/16" FR-4 board with 1oz. copper foil. It can be used as a rough guideline in estimating thermal resistance.

* Tab of device attached to topside copper

The thermal resistance for each application will be affected by thermal interactions with other components on the board. Some experimentation will be necessary to determine the actual value.

The power dissipation of the LT1117 is equal to:

\[ P_D = (V_{IN} - V_{OUT}) \cdot I_{OUT} \]

Maximum junction temperature will be equal to:

\[ T_J = T_{A(MAX)} + P_D(\text{Thermal Resistance (junction-to-ambient)}) \]

Maximum junction temperature must not exceed 125°C.

**Ripple Rejection**

The curves for Ripple Rejection were generated using an adjustable device with the adjust pin bypassed. These curves will hold true for all values of output voltage. For proper bypassing, and ripple rejection approaching the values shown, the impedance of the adjust pin capacitor, at the ripple frequency, should be \(< R_1 \). R1 is normally in the range of 100Ω-200Ω. The size of the required adjust pin capacitor is a function of the input ripple frequency. At 120Hz, with \( R_1=100Ω \), the adjust pin capacitor should be \( >13\mu F \). At 10kHz only 0.16µF is needed.

For fixed voltage devices, and adjustable devices without an adjust pin capacitor, the output ripple will increase as the ratio of the output voltage to the reference voltage \( V_{OUT}/V_{REF} \). For example, with the output voltage equal to 5V, the output ripple will be increased by the ratio of 5V/1.25V. It will increase by a factor of four. Ripple rejection will be degraded by 12dB from the value shown on the curve.

SOLDERING METHODS

The SOT-223 is manufactured with gull wing leadform for surface mount applications. The leads and heatsink are solder plated and allow easy soldering using non-active or mildly active fluxes. The package is constructed with three leads exiting one side of the package and one heatsink exiting the other side, and the die attached to the heatsink internally.

The recommended methods of soldering SOT-223 are: vapor phase reflow and infrared reflow with preheat of component to within 65°C of the solder temperature. Hand soldering and wave soldering are not recommended since these methods can easily damage the part with excessive thermal gradients across the package.

Care must be exercised during surface mount to minimize large (> 30°C per second) thermal shock to the package.
